Probabilistic Programs

Draw random data from distributions

Condition control-flow at random

◆□▶ ◆□▶ ◆ □▶ ◆ □▶ ○ □ ○ ○ ○ ○

High-Level Features:

- Functional (Borgström et al. 2016)
- Higher-order (Ehrhard, Pagani, and Tasson 2018)
- Recursive types (Vákár, Kammar, and Staton 2019)

Formal semantics has been well studied.

Low-Level Features:

- Imperative
- Unstructured control-flow

Operational semantics:

(Ferrer Fioriti and Hermanns 2015)

Denotational semantics: This work

Benefits of A Denotational Semantics

- Abstraction from details about program executions
- Compositionality

COMPILER

Example

The following code implements a variant of geometric distributions.

```
n := 0;
while prob(0.9) do
n := n + 1;
if n \ge 10 then break
else continue
od
```

There are multiple possible executions of the program, e.g., *n* could end up with 0, 3, or 10.

Principle

Probabilistic programs establish input/**output-distribution** relations. A probabilistic program can be modeled as a function in $X \to \mathcal{D}(X)$, where X is a program state space and $\mathcal{D}(X)$ consists of probability distributions over X.

< □ > < 同 > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > <

There are multiple possible executions of the program, e.g., *n* could end up with 0, 3, or 10.

Principle

Probabilistic programs establish input/**output-distribution** relations. A probabilistic program can be modeled as a function in $X \to \mathcal{D}(X)$, where X is a program state space and $\mathcal{D}(X)$ consists of probability distributions over X.

Nondeterminism

Sources

- Agents for Markov decisions processes (MDPs)
- Abstraction and refinement on programs

A Common Resolution

A nondeterministic function f from X to Y is a set-valued function that maps an input to a collection of outputs, i.e.,

 $f \in X \to \wp(Y).$

Nondeterminism in Probabilistic Programming

A nondeterministic function f from X to $\mathcal{D}(X)$ should have the signature

$$f \in X \to \wp(\mathcal{D}(X)),$$

▲□▶▲□▶▲□▶▲□▶ ▲□ ● のへで

where $\mathcal{D}(X)$ consists of probability distributions over *X*.

Nondeterminism

Sources

- Agents for Markov decisions processes (MDPs)

 $f\in X\to \wp(Y).$

Nondeterminism in Probabilistic Programming

A nondeterministic function f from X to $\mathcal{D}(X)$ should have the signature

$$f \in X \to \wp(\mathcal{D}(X)),$$

where $\mathcal{D}(X)$ consists of probability distributions over *X*.

When to Resolve Nondeterminism?

X is a program state space. $\mathcal{D}(X)$ consists of probability distributions over X.

The Common Resolution: Input Prior to Nondeterminism

 $f\in X\to \wp(\mathcal{D}(X))$

What about: Nondeterminism Prior to Input?

$$f \in \wp(X \to \mathcal{D}(X))$$

Intuition: A nondeterministic program is a specification that models a **collection** of deterministic refinements.

When to Resolve Nondeterminism?

X is a program state space. $\mathcal{D}(X)$ consists of probability distributions over X.

The Common Resolution: Input Prior to Nondeterminism

 $f\in X\to \wp(\mathcal{D}(X))$

What about: Nondeterminism Prior to Input?

 $f\in \wp(X\to \mathcal{D}(X))$

- コン・4回シュービン・4回シューレー

Intuition: A nondeterministic program is a specification that models a **collection** of deterministic refinements.

- コン・4回シュービン・4回シューレー

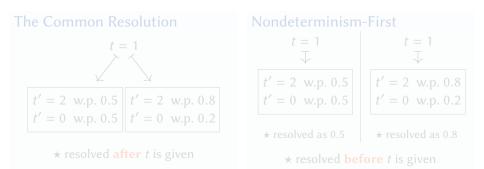

Intuition: A nondeterministic program is a specification that models a **collection** of deterministic refinements.

Nondeterminism-First: Nondeterminism Prior to Input

Example

Consider the following program P where \star represents nondeterminism.

if $prob(\star)$ then $t \coloneqq t + 1$ else $t \coloneqq t - 1$ fi

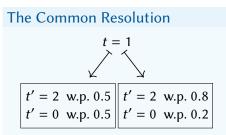

Nondeterminism-First: Nondeterminism Prior to Input

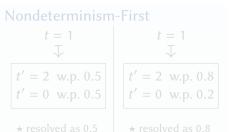

Example

Consider the following program P where \star represents nondeterminism.

if $prob(\star)$ then $t \coloneqq t + 1$ else $t \coloneqq t - 1$ fi

 \star resolved **after** *t* is given

▲□▶▲□▶▲□▶▲□▶ □ のQで

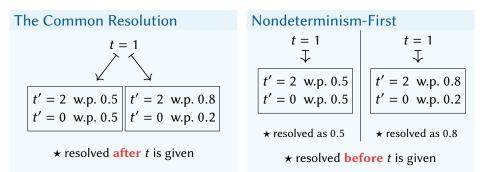

***** resolved **before** *t* is given

Nondeterminism-First: Nondeterminism Prior to Input

Example

Consider the following program P where \star represents nondeterminism.

if $prob(\star)$ then $t \coloneqq t + 1$ else $t \coloneqq t - 1$ fi

Nondeterminism-First: What's the Benefit?

Example

Consider the following program *P* where \star represents nondeterminism.

if $prob(\star)$ then $t \coloneqq t + 1$ else $t \coloneqq t - 1$ fi

Relational Reasoning about Refinements of a Program

- For all refinements *P'* of *P*, for all t_1, t_2 , can we prove that $\mathbb{E}_{t'_1 \sim P'(t_1), t'_2 \sim P'(t_2)}[t'_1 t'_2] = t_1 t_2$?
- For all refinements P' of P, for all t₁, t₂, does P' exhibit similar execution time on t₁ and t₂?

Nondeterminism-First: What's the Benefit?

Example

Consider the following program *P* where \star represents nondeterminism.

```
if prob(\star) then t \coloneqq t + 1 else t \coloneqq t - 1 fi
```

Relational Reasoning about Refinements of a Program

- For all refinements *P'* of *P*, for all t_1, t_2 , can we prove that $\mathbb{E}_{t'_1 \sim P'(t_1), t'_2 \sim P'(t_2)}[t'_1 t'_2] = t_1 t_2$?
- For all refinements *P*′ of *P*, for all *t*₁, *t*₂, does *P*′ exhibit similar execution time on *t*₁ and *t*₂?

Nondeterminism-First: What's the Benefit?

Example

Consider the following program *P* where \star represents nondeterminism.

if $prob(\star)$ then $t \coloneqq t + 1$ else $t \coloneqq t - 1$ fi

Relational Reasoning about Refinements of a Program

Contributions

- We develop a denotational semantics for **low-level** probabilistic programs with unstructured control-flow, general recursion, and nondeterminism.
- We study different resolutions for nondeterminism and propose a new model that involves nondeterminacy among state transformers.
- We devise an **algebraic** framework for denotational semantics, which can be instantiated with different resolutions for nondeterminism.

Outline

Motivation

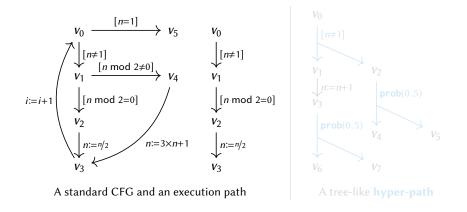

Control-Flow Hyper-Graphs

Algebraic Denotational Semantics

Nondeterminism-First

Representation of Low-Level Probabilistic Programs

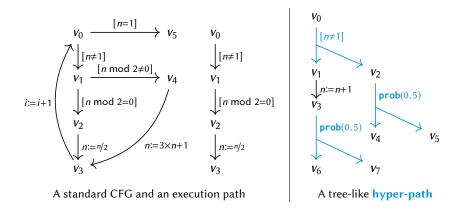

Principle

For probabilistic programs, execution paths are *not* independent. A formal semantics should reason about **distributions** over paths.

Control-Flow Hyper-Graphs

- Hyper-graphs are directed graphs with hyper-edges that could have multiple destinations. Hyper-paths are made up of hyper-egdes.
- The following hyper-graph

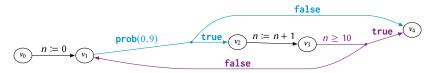

represents the control-flow of the example program

```
n := 0;
while prob(0.9) do
n := n + 1;
if n \ge 10 then break
else continue
od
```

Algebraic Denotational Semantics

◆□▶ ◆□▶ ◆ □▶ ◆ □▶ ─ □ ─ のへぐ

Nondeterminism-First

An Algebraic Denotational Semantics

Goal

Develop a denotational semantics that can be instantiated with different resolutions of nondeterminism.

An Algebraic Approach

- Perform reasoning in some **abstract** space of program states and state transformers.
- The state transformers should obey some algebraic laws.
- For example, the command **skip** should be interpreted as an **identity** element for sequencing in the algebra of transformers.

Outcome

The semantics is a good fit for developing static analyses (Wang, Hoffmann, and Reps 2018).

Principle

The semantics of a node in the control-flow hyper-graph is a summary of computation that **continues from** that node.

Recall the control-flow hyper-graph below.

Semantics is defined as the least solution to the following equation system

$$S(v_0) = seq[n := 0](S(v_1)) \qquad S(v_2) = seq[n := n+1](S(v_3)) \qquad S(v_4) = 1$$

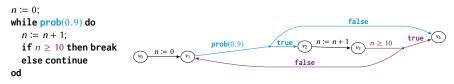

$$S(v_1) = prob[0.9](S(v_2), S(v_4)) \qquad S(v_3) = cond[n \ge 10](S(v_4), S(v_1))$$

▲□▶▲□▶▲□▶▲□▶ ■ のへ⊙

Reasoning with Nondeterminism-First

Example

Recall the following nondeterministic program P

```
if prob(\star) then t \coloneqq t + 1 else t \coloneqq t - 1 fi
```

Then the common resolution for nondeterminism derives

$$\lambda t.\{r \cdot \delta(t+1) + (1-r) \cdot \delta(t-1) \mid r \in [0,1]\},\$$

but the nondeterminism-first model leads to

$$\{\lambda t. r \cdot \delta(t+1) + (1-r) \cdot \delta(t-1) \mid r \in [0,1]\}.$$

With the new model, we can prove that for every refinement P' with \star resolved as $r \in [0, 1]$, for all t_1, t_2 , we have

$$\begin{split} \mathbb{E}_{t_1' \sim P'(t_1), t_2' \sim P'(t_2)}[t_1' - t_2'] &= \mathbb{E}_{t_1' \sim P'(t_1)}[t_1'] - \mathbb{E}_{t_2' \sim P'(t_2)}[t_2'] \\ &= (r(t_1 + 1) + (1 - r)(t_1 - 1)) - (r(t_2 + 1) + (1 - r)(t_2 - 1)) \\ &= t_1 - t_2 \end{split}$$

Reasoning with Nondeterminism-First

Example

Recall the following nondeterministic program P

```
if prob(\star) then t \coloneqq t + 1 else t \coloneqq t - 1 fi
```

Then the common resolution for nondeterminism derives

$$\lambda t.\{r \cdot \delta(t+1) + (1-r) \cdot \delta(t-1) \mid r \in [0,1]\},\$$

but the nondeterminism-first model leads to

$$\{\lambda t. r \cdot \delta(t+1) + (1-r) \cdot \delta(t-1) \mid r \in [0,1]\}.$$

With the new model, we can prove that for every refinement P' with \star resolved as $r \in [0, 1]$, for all t_1, t_2 , we have

$$\begin{split} \mathbb{E}_{t_1' \sim P'(t_1), t_2' \sim P'(t_2)}[t_1' - t_2'] &= \mathbb{E}_{t_1' \sim P'(t_1)}[t_1'] - \mathbb{E}_{t_2' \sim P'(t_2)}[t_2'] \\ &= (r(t_1 + 1) + (1 - r)(t_1 - 1)) - (r(t_2 + 1) + (1 - r)(t_2 - 1)) \\ &= t_1 - t_2 \end{split}$$

Necessary Conditions

We need to identify a subset \mathcal{A} of $\wp(\underline{\mathcal{K}}(X))$ as the collection of admissible semantic objects.

- \mathcal{A} admits a semilattice operation \forall (used as **nondeterministic-choice**), s.t. for all $A \in \mathcal{A}$, $A \forall A = A$.
- \mathcal{A} is equipped with a conditional-choice operation $_{\phi} \diamond$ where $\phi : X \rightarrow [0, 1]$ represents a Boolean-valued random variable.
- For all $A_1, A_2 \in \mathcal{A}$ and $\phi : X \to [0, 1]$, if $\kappa_1 \in A_1$ and $\kappa_2 \in A_2$, then $\kappa_1 {}_{\phi} \diamond \kappa_2$ should be in $A_1 \sqcup A_2$.

A Convexity-Like Condition

Necessary Conditions

We need to identify a subset \mathcal{A} of $\wp(\underline{\mathcal{K}}(X))$ as the collection of admissible semantic objects.

- A admits a semilattice operation
 ⊎ (used as nondeterministic-choice), s.t. for all A ∈ A, A ⊎ A = A.
- \mathcal{A} is equipped with a conditional-choice operation $_{\phi} \diamond$ where $\phi : X \rightarrow [0, 1]$ represents a Boolean-valued random variable.
- For all $A_1, A_2 \in \mathcal{A}$ and $\phi : X \to [0, 1]$, if $\kappa_1 \in A_1$ and $\kappa_2 \in A_2$, then $\kappa_1 {}_{\phi} \diamond \kappa_2$ should be in $A_1 \sqcup A_2$.

A Convexity-Like Condition

Necessary Conditions

We need to identify a subset \mathcal{A} of $\wp(\underline{\mathcal{K}}(X))$ as the collection of admissible semantic objects.

- A admits a semilattice operation
 ∪ (used as nondeterministic-choice), s.t. for all A ∈ A, A ∪ A = A.
- \mathcal{A} is equipped with a conditional-choice operation $_{\phi}$ where $\phi: X \to [0, 1]$ represents a Boolean-valued random variable.
- For all $A_1, A_2 \in \mathcal{A}$ and $\phi : X \to [0, 1]$, if $\kappa_1 \in A_1$ and $\kappa_2 \in A_2$, then $\kappa_1 {}_{\phi} \diamond \kappa_2$ should be in $A_1 \sqcup A_2$.

A Convexity-Like Condition

Generalized Convexity

Let $\phi \cdot \kappa \stackrel{\text{def}}{=} \lambda x . \lambda x' . \phi(x) \cdot \kappa(x)(x')$ and $\kappa_1 + \kappa_2 \stackrel{\text{def}}{=} \lambda x . \lambda x . \kappa_1(x)(x') + \kappa_2(x)(x')$. Then $\kappa_1 \phi \approx \kappa_2$ can be represented as $\phi \cdot \kappa_1 + (1 - \phi) \cdot \kappa_2$.

Definition

A subset *A* of $\underline{\mathcal{K}}(X)$ is said to be **g-convex**, if for all sequences $\{\kappa_i\}_{i\in\mathbb{N}} \subseteq A$ and $\{\phi_i\}_{i\in\mathbb{N}} \subseteq X \to [0, 1]$ such that $\sum_{i=1}^{\infty} \phi_i = i$, then $\sum_{i=1}^{\infty} \phi_i \cdot \kappa_i \in A$.

Clearly g-convexity of a set *A* implies that for all $\phi : X \to [0, 1]$ and $\kappa_1, \kappa_2 \in A$, we have $\kappa_1 \ _{\phi} \diamondsuit \ \kappa_2 \in A$.

Generalized Convexity

Let $\phi \cdot \kappa \stackrel{\text{def}}{=} \lambda x . \lambda x' . \phi(x) \cdot \kappa(x)(x')$ and $\kappa_1 + \kappa_2 \stackrel{\text{def}}{=} \lambda x . \lambda x . \kappa_1(x)(x') + \kappa_2(x)(x')$. Then $\kappa_1 \phi \approx \kappa_2$ can be represented as $\phi \cdot \kappa_1 + (1 - \phi) \cdot \kappa_2$.

Definition

Clearly g-convexity of a set *A* implies that for all $\phi : X \to [0, 1]$ and $\kappa_1, \kappa_2 \in A$, we have $\kappa_1 {}_{\phi} \diamondsuit \kappa_2 \in A$.

A G-Convex Powerdomain for Nondeterminism-First

Idea

Construct a Plotkin-style powerdomain on $\underline{\mathcal{K}}(X)$, *except that* g-convexity replaces standard convexity in the development.

Example

Consider the following nondeterministic program P

if
$$\star$$
 then $t \coloneqq t + 1$ else $t \coloneqq t - 1$ fi

Let the state space $X \stackrel{\text{def}}{=} \mathbb{Z}$ represent the value of *t*. The common resolution for nondeterminism gives the following semantics

$$\lambda t.\{r \cdot \delta(t+1) + (1-r) \cdot \delta(t-1) \mid r \in [0,1]\}$$

while the nondeterminism-first resolution derives

 $\{\lambda t.\phi(t)\cdot\delta(t+1)+(1-\phi(t))\cdot\delta(t-1)\mid\phi\in\mathbb{Z}\to[0,1]\}.$

while the nondeterminism-first resolution derives

 $\{\lambda t.\phi(t)\cdot \delta(t+1)+(1-\phi(t))\cdot \delta(t-1)\mid \phi\in\mathbb{Z}\rightarrow[0,1]\}.$

Summary

This Work

We have developed an **algebraic** framework for denotational semantics of **low-level** probabilistic programs, which can be instantiated with different models of nondeterminism, including the common resolution for nondeterminism and the new **nondeterminism-first**.

Limitations and Future Work

- The framework does not support for continuous distributions yet.
- We are looking for interesting applications of nondeterminism-first, especially for relational reasoning.

Summary
